tempered into a steel pdf

Differential tempering is a method of providing different amounts of temper to different parts of the steel. The method is often used in bladesmithing, for making knives and swords, to provide a very hard edge while softening the spine or center of the blade. This increased the toughness while maintaining a very hard, sharp, impact-resistant edge, helping to prevent breakage.

Martensite is named after the German metallurgist Adolf Martens (1850–1914). The term most commonly refers to a very hard form of steel crystalline structure, but can also refer to any crystal structure that is formed by diffusionless transformation. Martensite includes a class of hard minerals that occur as lath- or plate-shaped crystal grains.

Carbon steel, or plain-carbon steel, is a metal alloy. It is a combination of two elements, iron and carbon. Other
elements are present in quantities too small to affect its properties. The only other elements allowed in
plain-carbon steel are: manganese (1.65% max), silicon (0.60% max), and copper (0.60% max). Steel with a
low carbon content has the same properties as iron, soft but easily formed.
